

Yap architecture and data flows

Managed production mode | Michael Grinich | Source checkpoint: September 7, 2026

Direct Mac-to-Zoom path: browser authorization, REST requests and recording downloads; SDK meeting media
Content and recording passcodes do not pass through the authorization service.

Authentication exchange

- 1 The browser obtains user consent at Zoom and returns a code to Yap.
- 2 Yap sends code + PKCE verifier (or refresh token) to B. B calls Zoom's fixed token endpoint and returns OAuth tokens + a bound signing grant.
- 3 Yap sends access token + grant to B. B verifies the grant, checks live ZAK authorization at Zoom, then returns an expiring SDK JWT.
- 4 Yap uses Zoom directly for meetings and recordings. HTTPS media redirects drop OAuth authorization before a non-Zoom CDN target.

Service controls

120 requests/minute per hashed source IP;
10 signatures/minute per hashed token.
Bounded bodies; fixed upstreams; no redirects.
Constant error events only; invocation logs
and traces off. Platform metadata is separate.

Optional Google Calendar: Yap uses Google OAuth and read-only Calendar API directly; calendar content bypasses B.
